

SSL Certificate Rotation Automation

Operations Training Deck · Let's Encrypt on Windows Server & Azure Web Apps

NOC / Infrastructure Operations

Companion to the Cert-Man-Windows handbook

Start here

Which runbook do I use?

Pick the right path for any certificate based on what needs it and how it's exposed.

Public IIS website, port 80 reachable, no wildcard. win-acme issues, binds, and auto-renews.

Wildcard, internal host, or port 80 blocked. Validate via the DNS provider's API.

CNAME Delegation (no-API DNS)

No-API registrar (Network Solutions, etc.) or internal DNS? Add one CNAME for `_acme-challenge` to a zone you control. win-acme follows the CNAME automatically (AllowDnsSubstitution) — no acme-dns server needed.

RDP, SQL Server, Exchange, custom HTTP.SYS: renew, then a post-renewal script re-binds & restarts.

Azure Web App — Let's Encrypt (Posh-ACME)

Single hostname? Use Azure's free managed cert (auto-renews). For wildcard / export: our own Azure Automation runbook issues via Posh-ACME, uploads to Key Vault, App Service imports. No third-party app.

Monitoring & Alerting

Automation fails silently — dual-layer monitoring catches both the outage and its cause.

Runbook 08

Replacing an Existing Cert (any vendor)

Take over a self-signed default, GoDaddy, DigiCert, or any cert: Let's Encrypt issues fresh and re-binds. Inventory → cutover → clean up.

Runbook 09

acme-dns Server (no-API registrars at scale)

Optional MSP model: run one acme-dns server; every customer adds a single CNAME to it and all their certs auto-renew — whatever registrar they use. (For most cases, win-acme following a CNAME or Posh-ACME -DnsAlias needs no server.)
